## Career Services Assignment 3 – Java Flash Cards

**Points possible:** 50

Category	Criteria	% of Grade	
Completeness	All requirements of the	100	)
	assignment are complete.		

**Instructions:** Research common JavaScript interview questions online and create 20 flash cards from the information you find. Study your flash cards regularly to better prepare for interviews. Fill out the table below with the information you put on each of your flash cards.

Front of Card	Back of Card
JavaScript	Source: https://www.dotnettricks.com/learn/javascript/javascript-interview-questions
Interview	
Questions	
1. What is JavaScript?	Ans: JavaScript is an object-based programming language, mostly used as a client-side programming language with the HTML page to add some behavior to it.
	JavaScript was initially created as a browser-only language, but not it can be executed on the server or any client which has a JavaScript Engine. A product like Node.js, MongoDB, jaggery.js, ASP and many more use server-side JavaScript.
	In the browser, JavaScript can do many things as given below: # manipulating the HTML element
2. What is ECMASCript?	Ans. ECMAScript is a scripting language standardized by ECMA International-262. Languages like ActionScript, JavaScript, and many more scripting languages are used ECMAScript, among these JavaScript is a well known client-side language and an implementation of ECMAScript, since the standard was published. The latest version is ECMAScript6.
3. What are the data types supported by JavaScript?	Ans. JavaScript variables are dynamically typed, which means there is a data type but it will not be bound to a particular type. For example, while initializing the variable it can be string type, but later it can assign to a numeric value.
	There are two types of data types that are being supported which are primitive data types and non-primitive data types, below are some of the data types supported by JavaScript.
	The data types supported by JavaScript are:
	Undefined
	Null
	Boolean Object
	String
	Symbol
	Number
4. What is the difference	Ans. Consider below example
between	var x;

undefined and	<pre>console.log(x);</pre>
not defined?	console. log(x),
	Now in the console, we will get a message x is 'undefined' which means the variable is declared and memory is created but the value is not assigned to it.
	Console.log(y);
	In this case, you will get a message like 'not defined' because the variable y is not created, and memory is not allocated for it and we try to reference the variable.
5. What is the use of typeof operator?	Ans. The typeof is a unary operator which means it takes a single operand in a statement or expression, it is used to check the data type of its operand in the form of a string for example if we check the variable which is undefined then the typeof will return values as "undefined."
	<pre>var x=10; console.log(typeof (x));</pre>
	It will print the number in the console
	<pre>var x = 10; console.log(typeof(x) == 'number');</pre>
	From the above code if the typeof x is a number, so from the expression it will print true in the console.
6. What is the instanceof operator?	Ans. instanceof operator checks whether the object is an instance of a class or not.
operator:	<pre>Function Country(name) {this.name = name}; var country = new Country("India"); console.log(country instanceof Country) // return true;</pre>
	It will also consider inheritance.
	Let arr = ['apple', 'orange', 'grapes']; console.log(arr instanceof Array); //prints true in console console.log(arr instanceof Object); // prints true in console
	arr is an array, but it also belongs to the object, because array prototypal inherits from the object.
7. What is the strict mode?	Ans. "use strict" is not a statement but a literal expression which is supported by ECMAScript version 5. This statement instructs the browser to use the strict mode, which is a safer future in JavaScript. It will remove some JavaScript silent errors.
	The strict mode applies to the entire script or to the individual functions and it doesn't apply to the block statements or close which is enclosed by the curly braces {}. Attempting to apply it to such contexts does not have any meaning. At multiple places such as eval code, functional code, event handler attributes, strings passed along with the setTimeout() and related functions are completely scripts, and invoking the strict mode in them works as expected to check the syntax vulnerabilities.
	Example
	<pre>"use strict"; x = 10; //this will give error</pre>
	The above statement will give an error because in strict mode the variable

```
should be declared before it is used.
               The "use strict" expression can be in global scope as well as local scope
               Global scope
               const employee = {name: "Ram", age: 25}
               employee.name = "Raju" // it is possible
               "use strict"
               x = 10; this will give error
               Local scope
               x = 10; // this will not give error.
               MyFunction();
               function myFunction() {
                 "use strict";
               y = 15; // this will give error
               Ans. The group of characters or textual data is called a string, in
8. Explain
                JavaScript, there is no separate type for the character, even a single
string in
JavaScript?
               character will be stored as a string. In JavaScript, the string can be
               enclosed with single quotes or double-quotes.
               But with JavaScript, the methods and properties are also available to
               primitive values, because JavaScript treats primitive values as an object
               when executing the methods and properties.
               Var str = "hello";
                console.log(str); // print hello
               Ans. The differences between search() and indexOf() are given below:
9. What are
the
               Search():
differences
               It is used to find a specified value and returns the position of the match,
between
               the value can be a string or a regular expression.
search() and
indexOf()?
               var m = /e/;
               var str = "apple";
               str.search(m); // return 4
               indexOf():
               It is used to find a specified value and returns the position of the match,
               the value should be a string, it won't accept a regular expression.
               var m = 'e';
               var str = "apple";
                str.indexOf(m); // return -1
10. What are
               Ans: The differences between indexOf() and lastIndexOf() methods are given
               below:
the
differences
between
               indexOf():
indexOf() and
                It will return the index of the first occurrence of specific text in a
lastIndexOf()?
               string.
               var str = "Hello find me test me";
                str.indexOf("me"); // return 11
```

```
lastIndexOf() :
               It will return the index of the last occurrence of specific text in a
               strina.
               var str = "Hello find me test me";
                str.lastIndexOf("me"); // return 19
11. What are
               Ans. The Differences between substr and substring methods are given below:
the
differences
                substr():
                It is used to return the characters in a string beginning at the specified
between
substr() and
               index and returns the number of characters based on the length provided.
substring()?
               var x = "hello";
               console.log((x.substr(1, 4) == "ello"));
               // It will print true in the log
                substring() :
               It is used to return the characters in a string beginning at the specified
               index and returns the number of characters based on length provided-1.
               var x = "hello";
               console.log((x.substring(1, 4) == "ello"));
               // It will print false in the log
               var x = "hello";
               console.log((x.substring(1, 5) == "ello")) // prints true in the console
12. What are
               Ans. The differences between array and object are given below:
the
differences
               Array
               The array uses the numbered indexes to access the element in it;
between an
array and
               You should use an array when you want the element name to be a number;
object?
               It is an ordered collection.
               Object
               The object uses the named indexes to access the members in it;
               You should use an object when you want the element name to be a string;
               It is a collection of unordered properties.
13. What is
               Ans. The self-executing function will execute right after it has been
the self-
               defined. The advantage of using it is, that it will execute the code without
               declaring any global [??]. Mostly it will be used to attach event listeners
executing
               to DOM elements and other initialization work.
function?
               This type of self-executing of function does not have its own name and hence
               it is called an anonymous function. The function has a trailing set of
               parenthesis without any arguments. The parameters for this function could be
               passed in the parenthesis.
               Below is a simple example showing the usage of the anonymous function:
                (function ()
               // function body
               })();
14. What is
               Ans. The arrow function will support in JavaScript only after ES6 or above,
```

```
it is a short way to write function expressions. The conventional way of
the arrow
function?
               writing a function [?].
               The arrow function is basically a shorter syntax for using a function that
               does not have it's own "this", below is a simple example of the same:
               function add(a, b) {
                 return a + b;
               console.log(add(1, 2)); // returns 3
               Using arrow function:
               add = (a, b) => \{
                return a + b;
               console.log(add(1, 2)); // returns 3
               Ans. The window object navigator is used to find the browser which is
15. How to
find the
               currently running the web application.
browser which
is running the
               var browserName = navigator.appName;
               console.log(browserName);
web page?
16. How to
               Ans. We can use the window object location to redirect the user to the new
               page by providing the HREF URL link to be redirected to.
redirect the
user to a new
               Window.location.href="https://www.dotnettricks.com/"
page?
17. What is
               var num = "10";
                (function () {
the output of
               console.log("Original Number " + num);
the below
code?
               var num = 50";
               console.log("New Number " + num);
               })();
               Ans. Original number undefined.
               New Number 50
               Reason: You will expect the original number will take the value from the
               outer scope, but the salary value was undefined, *because of hoisting.*
               Ans. DOM is a W3C (World wide web consortium) standard, when the HTML page
18. What is
                loads in the browser, the browser creates the DOM (Document Object Model).
DOM?
               It defines the HTML element as an object and allows scripts to dynamically
               manipulate the content, and the structure of the document.
               When any of the HTML documents are loaded in the browser, it will become a
               document object which is the root element that represents the HTML document.
               Each DOM element has various properties and methods, and with the help of
               document objects, we may add dynamic content to our web page according to
               the required behavior.
               HTML:
               <!DOCTYPE html>
               <html lang="en">
                <body>
               <h1>Document Object Model</h1>
                </body>
               </html>
               In DOM, every HTML is an object, Nested tags are "children," the text inside
```

default object of the browser is a window. The various property provided by windows is a document, history, screen, location, and navigator.  All the modern browsers have implemented the same methods and properties for JavaScript operational interactions which are often referred to as a BOM's methods and properties. A window object is automatically created by the browser itself.  Ans. MaN property shows the "Not-a-Number" value. It shows a value that is not a legal number. One type of NaN would return a Number. If you want to check if a value is NaN, the isNaN() function is used. It is important to note that the isNaN() function transforms the given value to a Number type; later on, it equates to NaN.  Ans. A browser's history object could be used to switch to history pages like back and forward from the existing page or another page. 3 methods of history object are as follows:  1. history.bock() // this method loads the previous page 2. history, oforward() // this method loads the next page 3. history.go(number) // Its number may be positive (for forwarding) or negative (for backward). It will load the provided page number.  Ans. Timers are useful to work a piece of code at a specific time or iterate the code in a specific interval. The same is performed by using functions like setInterval, setTimeout, and clearInterval. Timers are executed in a single thread. So, maybe queue up and there may be a waiting time for execution.  The setTimeout(function, delay) function is useful for starting a timer that calls a specific function after the stated delay. The setInterval(function, delay) function frequently operates the provided function in the stated delay and only stops when canceled. The timer gets to know when to stop with the clearInterval language.  24. What is the various types of errors in JavaScript:  Ans. Here are the 3 types of errors in JavaScript: In the strict Mode, JavaScript displays errors for a segment of code that did not display an error string of the JavaScript engines.  You can enable Strict M		
The DOM represents HTML as a tree structure of tags. Here is how it looks in the browser "inspect the element." [no picture or words follow here.]  19. What is BOM?  Ans. BOM (Browser of Dipect Model) provides interaction with the browser, the default object of the browser is a window. The various property provided by windows is a document, history, screen, location, and navigator.  All the modern browsers have implemented the same methods and properties for Javascript operational interactions which are often referred to as a BOM's methods and properties. A window object is automatically created by the browser itself.  Ans. Ans property shows the "Not-a-Number" value. It shows a value that is not a legal number. One type of NaN would return a Number. If you want to check if a value is NaN, the ishann() function is used. It is important to note that the isNaN() function transforms the given value to a Number type; later on, it equates to NaN.  Ans. A browser's history object could be used to switch to history pages like back and forward from the existing page or another page. 3 methods of history object are as follows:  1. history.back() // this method loads the next page 3. history.go(number) // Its number may be positive (for forwarding) or negative (for backward). It will load the provided page number.  22. What is the working of times are useful to work a piece of code at a specific time or iterate the working of times are useful to work a piece of code at a specific time or iterate the code in a specific interval. The same is performed by using functions single thread. So, maybe queue up and there may be a waiting the for execution.  The setTimeout(function, delay) function is useful for starting a timer that calls aspecific function after the stated delay. The setInterval function, delay function frequently operates the provided function in the stated delay and only stops when canceled. The timer gets to know when to stop with the clearInterval (id) function.  Ans. Here are the 3 types of errors in JavaScr		a <n1> is an object as well.</n1>
the browser "inspect the element." [no picture or words follow here.]  Ans. BOM (Browser object Model) provides interaction with the browser, the default object of the browser is a window. The various property provided by windows is a document, history, screen, location, and navigator.  All the modern browsers have implemented the same methods and properties for JavaScript operational interactions which are often referred to as a BOM's methods and properties. A window object is automatically created by the browser itself.  Ans. NaN property shows the "Not-a-Number" value. It shows a value that is not a legal number. One type of NaN would return a Number. If you want to check if a value is NaN, the isNaN() function transforms the given value to a Number type; alter on, it equates to NaN.  Ans. A browser's history object could be used to switch to history pages like back and forward from the existing page or another page. 3 methods of history object are as follows:  1. history.back() // this method loads the previous page 2. history.go(number) // Its number may be positive (for forwarding) or negative (for backward). It will load the provided page number.  Ans. Itimers are useful to work a piece of code at a specific time or iterate the working of times in JavaScript?  Ans. Browser's history object are of code at a specific time or iterate the code in a specific interval. The same is performed by using functions like setInterval, setTimeout, and clearInterval firmers are executed in a single thread. So, maybe queue up and there may be a waiting time for execution.  The setTimeout(function, delay) function is useful for starting a timer that calls a specific function after the stated delay. In the strict Mode, JavaScript displays errors for a segment of code that did not display an error previously. However, it may be tricky and potentially insecure. Also, Strict Mode also resolves some errors that may obstruct the efficient working of the JavaScript engines.  You can enable Strict Mode by inserting the string literal "use strict" above the file. Look at the following example to get a better idea:  function myFunction() {  "use strict";  var v = "This shows implementation of strict mode function";  }	property in	check if a value is NaN, the isNaN() function is used. It is important to note that the isNaN() function transforms the given value to a Number type; later on, it equates to NaN.
1. history.back() // this method loads the previous page 2. history.forward() // this method loads the next page 3. history.go(number) // Its number may be positive (for forwarding) or negative (for backward). It will load the provided page number.  22. What is the working of timers in JavaScript?  Ans. Timers are useful to work a piece of code at a specific time or iterate the code in a specific interval. The same is performed by using functions like setInterval, setTimeout, and clearInterval. Timers are executed in a single thread. So, maybe queue up and there may be a waiting tme for execution.  The setTimeout(function, delay) function is useful for starting a timer that calls a specific function after the stated delay. The setInterval(function, delay) function frequently operates the provided function in the stated delay and only stops when canceled. The timer gets to know when to stop with the clearInterval(id) function.  Ans. Here are the 3 types of errors in JavaScript:  Runtime errors: These are the errors that occur due to misuse of the command within the HTML language.  Load time errors: These are the errors dynamically. Logical errors: These errors occur while loading a web page. An example includes improper syntax that produce the errors dynamically. Logical errors: These errors come up because of the bad logic carried out on a function with a varied operation.  Ans. Strict Mode inserts some compulsions to JavaScript. In the strict Mode, JavaScript displays errors for a segment of code that did not display an error previously. However, it may be tricky and potentially insecure. Also, Strict Mode also resolves some errors that may obstruct the efficient working of the JavaScript engines.  You can enable Strict Mode by inserting the string literal "use strict" above the file. Look at the following example to get a better idea:  function myFunction() {  "use strict";  var v = "This shows implementation of strict mode function";  }		like back and forward from the existing page or another page. 3 methods of
3. history.go(number) // Its number may be positive (for forwarding) or negative (for backward). It will load the provided page number.  Ans. Timers are useful to work a piece of code at a specific time or iterate the code in a specific interval. The same is performed by using functions like setInterval, setTimeout, and clearInterval. Timers are executed in a single thread. So, maybe queue up and there may be a waiting tme for execution.  The setTimeout(function, delay) function is useful for starting a timer that calls a specific function after the stated delay. The setInterval(function, delay) function frequently operates the provided function in the stated delay and only stops when canceled. The timer gets to know when to stop with the clearInterval(id) function.  Ans. Here are the 3 types of errors in JavaScript:  Runtime errors: These are the errors that occur due to misuse of the command within the HTML language.  Load time errors: These errors occur while loading a web page. An example includes improper syntax that produce the errors dynamically. Logical errors: These errors come up because of the bad logic carried out on a function with a varied operation.  24. What is the "Strict Mode in JavaScript displays errors for a segment of code that did not display an error previously. However, it may be tricky and potentially insecure. Also, Strict Mode also resolves some errors that may obstruct the efficient working of the JavaScript engines.  You can enable Strict Mode by inserting the string literal "use strict" above the file. Look at the following example to get a better idea:  function myFunction() {  "use strict"; var v = "This shows implementation of strict mode function";  }	object:	
negative (for backward). It will load the provided page number.  Ans. Timers are useful to work a piece of code at a specific time or iterate the working of timers in JavaScript?  Ans. Timers are useful to work a piece of code at a specific time or iterate the code in a specific interval. The same is performed by using functions like setInterval, setTimeout, and clearInterval. Timers are executed in a single thread. So, maybe queue up and there may be a waiting tme for execution.  The setTimeout(function, delay) function is useful for starting a timer that calls a specific function after the stated delay. The setInterval(function, delay) function frequently operates the provided function in the stated delay and only stops when canceled. The timer gets to know when to stop with the clearInterval(id) function.  Ans. Here are the 3 types of errors in JavaScript:  Runtime errors: These are the errors that occur due to misuse of the command within the HTML language.  Load time errors: These errors occur while loading a web page. An example includes improper syntax that produce the errors dynamically.  Logical errors: These errors come up because of the bad logic carried out on a function with a varied operation.  Ans. Strict Mode inserts some compulsions to JavaScript. In the strict Mode, JavaScript displays errors for a segment of code that did not display an error previously. However, it may be tricky and potentially insecure. Also, Strict Mode also resolves some errors that may obstruct the efficient working of the JavaScript engines.  You can enable Strict Mode by inserting the string literal "use strict" above the file. Look at the following example to get a better idea:  function myFunction() { "use strict"; var v = "This shows implementation of strict mode function"; }

		<pre>"use strict"; var v = "This shows implementation of strict mode function";</pre>
23. Experimental Anno. The function supply () and scale() are very then there usage but	25. Explain	Ans. The function .apply() and .call() are very identical in their usage but

the difference between .call( ) and .apply()	comes with a minor difference. The .call() is employed whenever a programmer knows the number of the function's arguments. This is because they have to be stated as arguments within the call statement. Conversely, .apply() is employed whenever the number is unknown. Also, this function .apply() needs that the argument should be an array. The key difference between these two functions is how the arguments are passed to the function.
26. How is DOM used in JavaScript?	Ans. DOM (Document Object Model) is accountable for how different objects in a model interrelate with each other. It is useful for developing web pages that contain objects like links, paragraphs, etc. Such objects can be executed to contain actions like add or delete. Furthermore, DOM is also useful to equip a web page with extra capabilities. The use of API provides a benefit compared to other prevailing models. If you deeply go through the JavaScript tutorial, you can know more about DOM.
27. What is the role of deferred scripts in	Ans. The parsing of HTML code during page loading is by default paused until the script has not halted executing. The webpage is delayed if the server is slow or the script is chiefly heavy.
JavaScript?	When using the Deferred, scripts would delay execution of the script until the HTML parser is operating. It decreases the web pages' loading time and they get showcased faster.
28. What are the different functional components in	Ans. Functional components are important topics covered in a JavaScript Course. Two type of functional components in JavaScript are – first class functions and nested functions.
JavaScript?	i. First class functions: these functions in JavaScript are used as first-class objects. Usually, this means that such functions can be passed in form of arguments to other functions. Also, they are returned as values from other functions or assigned to variables, or they can be saved in data structures.
	ii. Nested functions: Those functions that are defined within other functions are termed nested functions. Whenever the main function is invoked, nested functions are called.
29. What are the different ways to access the HTML	Ans. The following DOM Methods are used to capture the HTML element and manipulate it:  1.
elements in JavaScript?	getElementById('idname') - > this function is used to select the HTML element based on ID property of the HTML element.
	html <html> <head></head></html>
	<title></title> <body></body>
	<pre><label id="myelement"></label>   <script>    document.getElementById('myelement').innerHTML = '<h3> Welcome </h3>'   </script> </pre>
	getElementsByClassName('className') - > This function is used to select the HTML elements based on the class name in DOM, it will return all matched HTML elements with respect to the class name.
	html

```
<html>
                <head>
                  <meta charset="utf-8" />
                  <title></title>
                  <stvle>
                    .lblMsg {
                    color: #000;
                  </style>
                // does style go in head?
                </head>
                <body>
                  <label id="myelement" class="lblMsg"></label>
                  <script>
                       document.getElementByClassName("lblMsg")[0].innerHTML = '<h3> Welcome
                </h3>
                </script>
                </body>
                </html>
                getElementsByTagName('HTMLtagname') - > This function is used to select the
                HTML elements based on the Tag name in the DOM, it will return all matched
                HTML elements with respect to the tag name.
                <!DOCTYPE html>
                <html>
                <head>
                  <meta charset="utf-8" />
                  <title></title>
                </head>
                <style>
                  .lblMsg {
                  color: #000;
                  }
                </style>
                <body>
                  <label id="myelement" class"lblMsg"></label>
                <script>
                      document.getElementsByTagName('label')[0].innerHTML = '<h3> Welcome
                </h3>'
                </script>
                </body>
                </html>
                Ans. splice(), filter(), map(), isNaN(), indexOf(), lastIndexOf(),
30.

C++
Interview
Questions
1. What are
               Ans. The 4 data types in C++ are given below:
```

the different	a-Primitive Datatype(basic datatype). Example- char, short, int, float,
data types present in C+	long, double, bool, etc.
+?	b-Derived datatype. Example- array, pointer, etc. c-Enumeration. Example- enum
	d-User-defined data types. Example- structure, class, etc.
2. What is the difference between C and C++?	Ans. Main differences: C – procedure oriented language C++ - object oriented
CTT?	C – does not support data hiding C++ - Data is hidden by encapsulation to ensure that data structures and operators are used as intended.
	C – is a subset of C++ C++ - is a superset of C
	C – Function and operator overloading are not supported in C C++ - Function and operator overloading is supported in C++
	C – Namespace features are not present in C C++ - Namespace is used by C++, which avoids name collisions
	C – Functions can not be defined inside structures C++ - Functions can be defined inside structures.
	C - calloc() and malloc() functions are used for memory allocation and free() function is used for memory deallocation C++ - new operator is used for memory allocation and deletes operator is used for memory deallocation.
3. What are class and object in C++?	Ans. A class is a user-defined data type that has data members and member functions. Data members are the data variables and member functions are the
	An object is an instance of a class. Since a class is a user-defined data type so an object can also be called a variable of that data type.
	A class is defined as-
	<pre>class A{ private:    int data; public:    void fun(){</pre>
	};
4. What is the	For example, the following is a class car that can have properties like name, color, etc. and they can have methods like speed().  Ans. In C++ a structure is the same as a class except for a few differences
difference between struct	like security. The difference between struct and class are given below:
and class?	Structure a: members of the structures are public by default Class a:
	members of the class are private by default
	Structure b: when deriving a struct from a class/struct, default access specifiers for

```
base class/struct are publicly
                Class b:
                when deriving a class, default access specifiers are private.
                Ans. Operator Overloading is a very essential element to perform the
5. What is
                operations on user-defined data types. By operator overloading we can modify
operator
                the default meaning to the operators like +, -, *, /, <=, etc.
overloading?
                For Example -
                The following code is for adding two complex number using operator
                overloading-
                class complex{
                private:
                 float r, I;
                public:
                 complex(float r, float i){
                   this->r=r;
                   this->i=i;
                 }
                 complex() {}
                 void displaydata(){
                   cout<<"real part = " <<r<<endl;</pre>
                   cout<<"imaginary part = "<<i<endl;</pre>
                 complex operator+(complex c){
                   return complex(r+c.r, i+c.i);
                };
                int main (){
                complex a(2, 3);
                complex b(3, 4);
                complex c=a+b;
                c.displaydata();
                return 0;
                }
6. What is
                Ans. Polymorphism in simple means having many forms. Its behavior is
polymorphism
                different in different situations. And this occurs when e have multiple
in C++?
                classes that are related to each other by inheritance.
                For example, think of a base class called a car that has a method called car
                brand(). Derived classes of cars could be Mercedes, BMW, Audi - and they
                also have their own implementation of cars.
                The two types of polymorphism in C++ are:
                -Compile Time Polymorphism
                -Runtime Polymorphism
                Ans. The constructor is a member function that is executed automatically
7. Explain
constructor in
                whenever an object is created. Constructors have the same name as the class
C++
                of which they are members so that the compiler knows that the member
                function is a constructor. And no return type is used for constructors.
                class A {
                 private:
                  int val;
                 public:
                  A(int x){
                   val=x;
                 int main(){
                  A a(3);
```

```
return 0;
                 }
                };
8. Tell me
                Ans. Virtual function is a member function in the base class that you
                redefine in a derived class. A virtual function is declared using the
about virtual
function.
                virtual keyword. When the function is made virtual, C++ determines which
                function is to be invoked at the runtime based on the type of the object
                pointed by the base class pointer.
9. Compare
                Ans. The main difference between compile-time and runtime is provided below:
compile time
polymorphism
                A. Compile-time polymorphism: In this method, we would come to know at
and Runtime
                compile time which method will be called. And the call is resolved by the
polymorphism
                compiler.
                A. Runtime polymorphism: In this method, we come to know at run time which
                method will be called. The call is not resolved by the compiler.
                B. Compile-time polymorphism: It provides fast execution because it is known
                at the compile time.
                B. Runtime polymorphism: It provides slow execution compared to compile-time
                polymorphism because it is known at the run time.
                C. Compile-time polymorphism: It is achieved by function overloading and
                operator overloading.
                C. Runtime polymorphism: It can be achieved by virtual functions and
                pointers.
                D. Compile-time polymorphism: Example -
                int add(int a, int b){
                  return a+b;
                int add (int a, int b, int c){
                  return a+b+c;
                int main(){
                  cout<<add(2, 3)<<endl;</pre>
                  cout << add(2, 3, 4) << endl;
                  return 0;
                }
                D. Runtime polymorphism: Example -
                class A{
                  public:
                    virtual void fun(){
                      cout<<"base ";
                class B: public A{
                  public:
                    void fun(){
                      cout<<"derived ";</pre>
                };
                int main(){
                  A *a=new B;
                  a->fun();
                  return 0;
```

```
}
10. What do
                Ans. A friend class can access private, protected, and public members of
you know about
                other classes in which it is declared as friends.
friend class
and friend
                Like friend class, friend function can also access private, protected, and
function?
                public members. But, Friend functions are not member functions.
                For example -
                class A{
                  private:
                    int data_a;
                  public:
                    A(int x){
                      data_a=x;
                    friend int fun(A, B);
                class B{
                  private:
                    int data_b;
                  public:
                    A(int x){
                      data_b=x;
                  friend int fun(A, B);
                int fun(A a, B b){
                  return a.data_a+b.data_b;
                int main(){
                  A a(10);
                  B b(20);
                  cout<<fun(a, b)<<endl;</pre>
                  return 0;
                }
                Here we can access the private data of class A and class B.
11. What are
                Ans. In C++ there are the following access specifiers:
the C++ access
specifiers?
                Public: All data members and member functions are accessible outside the
                class.
                Protected: All data members and member functions are accessible inside the
                class and to the derived class.
                Private: All data members and member functions are not accessible outside
12. Define
                Ans. If a function is inline, the compiler places a copy of the code of that
                function at each point where the function is called at compile time. One of
inline
function
                the important advantages of using an inline function is that it eliminates
                the function calling overhead of a tradition function.
13. What is a
                Ans. A reference is like a pointer. It is another name of an already
reference in
                existing variable. Once a reference name is initialized with a variable,
C++?
                that variable can be accessed by the variable name or reference name both.
                For example -
```

	int x=10; int &ref=x; //reference variable
	If we then change the value of ref it will be reflected in x. Once a reference variable is initialized it cannot refer to any other variable. We can declare an array of pointers, but an array of references is not possible.
14. What do you mean by abstraction in C++?	Ans. Abstraction is the process of showing the essential details to the user and hiding the details which we don't want to show to the user or hiding the details which are irrelevant to a particular user.
15. Is deconstructor overloading possible? If yes, then explain and if no then why?	Ans. No deconstructor overloading is not possible. Deconstructors take no arguments, so there's only one way to destroy an object. That's the reason destructor overloading is not possible.
16. What do you mean by call by value and call by	Ans. In call by value method, we pass a copy of the parameter is passed to the functions. For these copied values a new memory is assigned and changes made to these values do not reflect the variable in the main function.
reference?	In call by reference method, e pass the address of the variable and the address is used to access the actual argument used in the function call. So changes made in the parameter alter the passing argument.
17. What is an abstract class and when do you use it.	
18. What are destructors in C++?	Ans. A constructor is automatically called when an object is first created. Similarly when an object is destroyed a function called destructor automatically gets called. A destructor has the same name as the constructor (which is the same as the class name) but is preceded by a tilde.
10 What are	<pre>Example:     class AP{         private:             int val;         public:             A(int x){             val=x;         }         A(){         }         -A(){ //destructor         }     }     int main(){         A a(3);         return 0;     } }</pre>
19.What are the static members and static member functions?	Ans. When a variable in a class is declared static, space for it is allocated for the lifetime of the program. No matter how many objects of that class have been created, there is only one copy of the static member. So same static member can be accessed by all the objects of that class.
	A static member function can be called even if no objects of the class exist and the static function are accessed using only the class name and the scope resolution operator ::

20. Explain inheritance	Ans. Inheritance is the process of creating new classes, called derived classes, from existing classes. These existing classes are called base classes. The derived classes inherit all the capabilities of the base class but can add new features and refinements of their own.
	Example - Class Vehicle fuelAmount() capacity() applyBrakes()
	Class Bus Class Car Class Truck
	Class Bus, Class Car, and Class Truck inherit the properties of Class Vehicle. The most important thing about inheritance is that it permits code reusability.
21. What is a copy constructor?	Ans. A copy constructor is a member function that initializes an object using another object of the same class.
	<pre>Example - class A{ int x,y;    A(int x, int y){    this-&gt;x=x;    this-&gt;y=y;</pre>
	};
	<pre>int main(){ A a1(2, 3); A a2=a1; //default copy constructor is called return 0; }</pre>
	We can define our copy constructor. If we don't define a copy constructor then the default copy constructor is called.
22. What is the difference	Ans. The difference between shallow copy and a deep copy is given below:
between shallow copy and deep copy?	Shallow Copy A: Shallow copy stores the references of objects to the original memory address.  Deep Copy A: Deep copy makes a new and separate copy of an entire object with its unique memory address.
	Shallow Copy B: Shallow copy is faster. Deep Copy B: Deep copy is comparatively slower.
	Shallow Copy C: Shallow copy reflects changes made to the new/copied object in the original object.  Deep Copy C: Deep copy doesn't reflect changes made to the new/copied object in the original object.
23. What is the difference between	Ans. A virtual function is a member function in the base class that you redefine in a derived class. It is declared using the virtual keyword.
virtual functions and	Example -
pure virtual functions?	<pre>class base{ public:</pre>
L	virtual void fun(){

```
};
                A pure virtual function is a function that has no implementation and is
                declared by assigning 0. It has no body.
                Example -
                class base{
                public:
                  virtual void fun()=0;
                };
                Here, = sign has got nothing to do with the assignment, and value 0 is not
                assigned to anything. It is used to simply tell the compiler that a function
                will be pure and it will not have any body.
24. If class D
                Ans. The derived class has two parts, a base part, and a derived part. When
is derived
                C++ constructs derived objects, it does so in phases. First, the most-base
from a base
                class (at the top of the inheritance tree) is constructed. Then each child
                class is constructed in order until the most-child class is constructed
class B, when
                last.
creating an
object of type
                So the first constructor of class B will be called and then the constructor
D in what
order would
                of class D will be called.
the
                During the destruction exactly reverse order is followed. That is destructor
constructors
                starts at the most-derived class and works its way down to base class.
of these
classes get
                So the first destructor class of class D will be called and then the
called?
                destructor of class B will be called.
25. Can we
                Ans. Yes, we can call a virtual function from a constructor. But the
call a virtual
                behavior is a little different in this case. When a virtual function is
                called, the virtual call is resolved at runtime. It is always the member
function from
a constructor?
                function of the current class that gets called. That is the virtual machine
                doesn't work within the constructor.
                For example -
                class base{
                  private:
                    int value;
                  public:
                    base(int x){
                      value=x;
                    virtual void fun(){
                    }
                class derived{
                  private:
                    int a;
                  public:
                    derived(int x, int y):base(x){
                      base *b;
                      b=this;
                      b->fun(); //calls derived::fun()
                }
                    void fun(){
```

```
cout<<"fun inside derived class"<<endl;</pre>
                    }
26. What are
                Ans. A void pointer is a pointer which is having no datatype associated with
void pointers?
                it. It can hold addresses of any type.
                For example-
                void *ptr;
                char *str;
                         // no error
                p=str;
                          // error because of type mismatch
                str=p;
                We can assign a pointer of any type to a void pointer but the reverse is not
                true unless you typecast it as
                str=(char*) ptr;
27. What is
                Ans. The member functions of every object have a pointer named this, which
                points to the object itself. The value of this is set to the address of the
this pointer
in C++?
                object for which it is called. It can be used to access the data in the
                object it points to.
                Example -
                class A{
                  private:
                    int value;
                  public:
                    void setvalue(int x){
                      this->value=x;
                };
                int main(){
                  A a;
                  a.setvalue(5);
                  return 0;
28. How do you
                Ans. The new operator is used for memory allocation and deletes operator is
allocate and
                used for memory deallocation in C++.
deallocate
memory in C++?
                For example -
                int value=new int;
                // allocates memory for storing 1 integer
                delete value;
                // deallocates memory taken by value
                int *arr=new int[10];
                // allocates memory for storing 10 intended
                delete []arr;
                // deallocates memory occupied by arr
```

Interview Questions	Source: <a href="https://www.whizlabs.com/blog/top-linux-interview-questions-answers/">https://www.whizlabs.com/blog/top-linux-interview-questions-answers/</a>
1. What is Linux and also explain the basic components of Linux?	Answer: Linux is the most commonly used operating system that is open source and free. For any computer, the operating system acts as the backbone, and it is most important software that is required for any computer. From network routers, television, video games console, smartwatches, smartphones, desktops, laptops to any other electronic device, Linux is everywhere.  Linux operating system is consist of 3 components which are as below:
2. What are the differences between UNIX and Linux	Kernel: Linux is a monolithic kernel that is free and open source software that is responsible for managing hardware resources for the users. System Library: System Library plays a vital role because application programs access Kernels feature using system library. System Utility: System Utility performs specific and individual level tasks. Answer: To understand the differences between UNIX and Linux Operating system, first of all, we should know that Linux is a UNIX clone, the Kernel of which is created by Linus Torvalds. There are so many differences between Linux and UNIX operating system which are as follows:
Operating System?	Open Source Operating System: The most significant difference between UNIX and Linux operating system is Linux is an open source operating system. The open-source operating system that means Linux source code is available for use so that developers can modify it as per their requirement. But UNIX operating system doesn't come under the broad category of an open-source operating system for which developers can edit it.
	Free of Cost: One of the biggest reason that it is broadly used is Linux operating system is free of cost. Linux operating system is free, but UNIX Operating system is not free. We can download it from the internet.
	Compatibility and Flexibility: If we compare the flexibility and compatibility of both operating system, you will find that Linux is more flexible than UNIX operating system and more compatible with different types of hardware as compared to UNIX operating System.
3. Describe BASH.	Answer: BASH stands for Bourne Again Shell. BASH is the UNIX shell for the GNU operating system. So, BASH is the command language interpreter that helps you to enter your input, and so you can retrieve information. In a straightforward language, we can say that it is a program that will understand the data entered by the user and execute the command and gives output.
4. What is crontab and explain its functionality and explain	Answer: Cron is a scheduler that executes the commands at a regular interval as per the specific date and time defined. We have multiple users in Linux, and all the users can have their crontab separately. The crontabs files are saved at a particular location that is /var/spool/cron/crontabs.
the format of crontab?	There are six fields in the format for the crontab that is as below:
	<pre><minute><hour><day_of_the_month><month_of_the_year><day_of_the_week><command execute="" program="" to=""/></day_of_the_week></month_of_the_year></day_of_the_month></hour></minute></pre>
1. Why LVM is	Ans: LVM stands for Logical Volume Manager, to resize file system's size

required ?	online we require LVM partition in Linux. Size of LVM partition can be extended and reduced the lvextend and lvreduce commands respectively.
2. How to check memory stats and CPU stats?	Ans: Using 'free' & 'vmstat' command we can display the physical and virtual memory statistics respectively. With the help of 'sar' command we see the CPU utilization & other stats.
3. What does Sar provides and at which location Sar logs are stored?	Ans: Sar collect, report, or save system activity information. The default version of the sar command (CPU utilization report) might be one of the first facilities the user runs to begin system activity investigation, because it monitors major system resources. If CPU utilization is near 100 percent (user + nice + system), the workload sampled is CPU-bound.
	By default log files of Sar command is located at /var/log/sa/sadd/ file, where the dd parameter indicates the current day.
4. How to increase the size of LVM partition?	Ans: Below are the Logical Steps: # use the lvextend command (lvextend -L +100M /dev/ <name lvm="" of="" partition="" the=""> , in this example we are extending the size by 100MB.) # resize2fs /dev/<name lvm="" of="" partition="" the=""> -check the size of partition using df command</name></name>
5. How to reduce or shrink the size of LVM partition?	Ans: Below are the logical steps to reduce size of LVM partition: # Unmount the filesystem using umount command [umount or unmount?] # Use resize2fs command, e.g. resize2fs /dev/mapper/myvg-mylv 10G # Now use the lvreduce command, e.g. lvreduce L 10G dev/mapper/myvg-lv Above Command ^ will shrink the file system and make the filesystem size 10GB.
6. How to create partition on the raw disk?	Ans: Using fdisk utility we can create partitions on the raw disk. Below are the steps to create partition: # fdisk dev/hd* (IDE) or dev/sd* (SCSI) # Type n to create a new partition. # After creating partition, type w command to write the changes to the partition table. # Type 'partprobe' to instruct the kernel to re-read the partition table.
7. Where are the kernel modules located?	Ans: The '/lib/modules/kernel-version/' directory stores all kernel modules or compiled drivers in Linux operating system. Also with 'lsmod' command we can see all the installed kernel modules.
8. What is umask?	Ans: umask stands for 'User file creation mask,' which determines the settings of a mask that controls which file permissions are set for files and directories when they are created.
9. How to set the umask permanently for a user?	Ans: To set this value permanently for a user, it has to be put in the appropriate profile which depends on the default shell of the user.
10. How to Boot RHEL / Rocky Linux / CentOS in Single User Mode?	Ans: Follow the beneath steps to boot RHEL / Rocky Linux / CentOS in single user mode:  # Reboot and go to the grub prompt  # Go to the end of line which starts with 'linux' and type 'rd.break' and hit enter.  # Mount the root file system in rw mode and then do chroot/sysroot.  # Perform the troubleshooting
11. How to share a directory using nfs	Ans: To share a directory using nfs, # First edit the configuration file '/etc/exportfs', add a entry like # / <directory-name> <ip network="" or="">(Options) # Restart the nfs service or 'exportfs -arv'</ip></directory-name>
12. How to check and mount nfs share?	Ans: Using 'showmount' command we can see which directories are shared via nfs e.g. 'showmount -e <ip address="" nds="" of="" server="">' Using mount command we can mount the nfs share on Linux machine.</ip>
13. What are	Ans: Default ports are listed below:

the default	# Service   Port
ports used for	# SMTP 25
SMTP, DNS,	# DNS 53
	# FTP 20 (data transfer), 21 (Connection established)
and squid?	# DHCP 67/UDP(dhcp server), 68/UDP(dhcp client)
	# SSH 22
	# Squid 3128
14. What is	Ans: Network bonding is the aggregation of multiple lan cards into a single
Network	bonded interface to provide fault tolerance and high performance. Network
Bonding?	bonding is also known as NIC Teaming.
15. What are	Ans: Below are the list of modes used in network bonding:
the different	# balance-rr or 0 – round-robin mode for fault tolerance and load balancing
modes of	# active-backup or 1 – Sets active-backup moder for fault tolerance
Network	# balance-xor or 2 – Sets an XOR (exclusive-or) mode for fault tolerance and
bonding in	load balancing.
Linux?	# broadcast or 3 – Sets a broadcast mode for fault tolerance. All
	transmissions are sent on all slave interfaces.
	# 802.3ad or 4 – Sets an IEEE 802.3ad dynamic link aggregation mode. Creates
	aggregation groups that share the same speed & duplex settings.
	# balance-tlb or 5 - Sets a Transmit Load Balancing (TLB) mode for fault
	tolerance & load balancing.
	# balance-alb or 6 - Sets and Active Load Balancing (ALB) mode for fault
10 11:	tolerance & load balancing.
16. How to	Ans: Using the command 'cat /proc/net/bonding/bond0', we can check which
check and	mode is enabled and what lan cards are used in this bond. In this example we
verify the	have only one bond interface but we can have multiple bond interfaces like
status of the	bond1, bond2 and so on.
bond	
interface?	Anguillaing the commande (notatet and /in route charl and /route alive con
check default	Ans: Using the commands 'netstat -nr', 'ip route show' and 'route -n' we can see the default route and routing tables.
route and	see the derautt route and routing tables.
routing table?	
18. How to	Ans: With the help of 'ss', 'netstat -listen' and 'lsof -i' commands we can
check which	check ports listening status.
ports are	check ports tisteming status.
listening in	
my Linux	
Server?	
19. What is	Ans: Default data directory for docker containers are '/var/lib/docker'.
default data	This behave duck directory for docker containers are Truly docker i
directory for	
docker	
containers?	
20. What is	Ans: Docker is a daemon based process, it means containers will only work
the difference	when docker daemon is running, whereas Podman is daemon-less, it means
between Docker	containers don't need any daemon to run.
and Podman?	
21. How to	Ans: We should never upgrade Linux Kernel, always install the new kernel
upgrade Kernel	using dnf (or yum) or rpm command because upgrading a kernel can make your
in Linux?	linux box in an unbootable state.
22. How to	Ans: There are two ways to scan newly assigned luns:
scan newly	# Method 1: if sg3 rpm is installed, then run the command 'rescan-scsi-
assigned luns	bus.sh'
on Linux box	# Method 2: Run the Command, 'echo "" > /sys/class/scsi_host/hostX/scan'
without	· · · · · · · · · · · · · · · · · · ·
rebooting?	
23. How to	Ans: We can find the WWN numbers of HBA cards using the command 'systool -c
find WWN	fc_host -v   grep port_name'
numbers of HBA	
L	

cards in Linux Server?	
24. How to add & change the Kernel parameters?	Ans: To set the kernel parameters in linux, first edit the file '/etc/sysctl.conf' after making the changes save the file and run the command 'sysctl -p', this command will make the changes permanently without rebooting the machine.
25. What is Puppet Server?	Ans: Puppet is an open-source & enterprise software server for configuration management toll in UNIX like operating system. Puppet is an IT automation software used to push configuration to its clients (puppet agents) using code. Puppet code can do a variety of tasks from installing new software, to check file permissions, or updating user accounts & lots of other tasks.
26. What are manifests in Puppet?	Ans: Manifests in Puppet are the files in which the client configuration is specified.
27. Which Command is used to sign requested certificates in Puppet Server?	Ans: 'puppetca -sign hostname-of-agent' in (2.X) & 'puppet ca sign hostname-of-agent' in (3.X)
28. How and Where to use Ansible ad-hoc commands?	Ans: Use the following syntax to use ansible ad-hoc command:  # \$ ansible [pattern] -m [module] -a <module option="">  # \$ ansible webservers -m shell -a 'df -Th'  Ad hoc commands are used for performing quick tasks and tests. We don't need to write any playbook to run ad-hoc commands on ansible hosts.</module>
29. How to find all the files under /var whose size is more than 200MB?	Ans: With the help of find command, we can list all the filds whose size is more than 200MB, # \$ sudo find /var -type f -size +100M -exec ls -lah {} \;
30.What is load average in Linux?	Ans: Load Average is defined as the average sum of the number of processes waiting in the run queue and number of processes currently executing over the period of 1, 5, and 15 minutes. Using the 'top' and 'uptime' command we find the load average of a Linux server.
